

The logo features a large, stylized red graphic element on the left, resembling a square with a horizontal bar extending to the right and a vertical bar extending downwards. The year '2018' is written vertically in light blue text within the vertical bar. To the right of the graphic, the word 'NATIONAL' is written in light blue, uppercase letters. Below 'NATIONAL', the name 'RYAN WHITE' is written in large, bold, white, uppercase letters. Underneath 'RYAN WHITE', the text 'CONFERENCE ON HIV CARE & TREATMENT' is written in light blue, uppercase letters. The entire logo is set against a dark blue background with a vertical red bar on the far left and a horizontal red bar at the bottom.

**2018** NATIONAL

CONFERENCE ON HIV CARE & TREATMENT

# Using Standardization and Analysis of HIV Quality Measures Data to Identify Treatment Gaps and Disparities

**Tammie L. Nelson & Samir Parmar**

*Epidemiology Department*

*Marion County Public Health Department, Indianapolis, IN*

# Learning Objectives

- Root cause analysis for improving patient care
- Best practices for improving clinical care using data standardization and analytic methods with HIV quality measures data
- Identification and evaluation of treatment gaps and health disparities in patient populations

# Why Evaluate Community Viral Load?

- Viral load suppression is the ultimate measure of health for individuals living with HIV<sup>1</sup>
- Comparing viral load results over time or between groups requires evaluation of community viral load (CVL) – an average of all viral load results taken from among those in the populations compared
- CVL analysis is important in identifying disparities in HIV care outcomes

<sup>1</sup> White House Office of National AIDS Policy. (2015). National HIV/AIDS strategy for the United States: Updated to 2020. <https://files.hiv.gov/s3fs-public/nhas-update.pdf>

# Barriers to Analysis

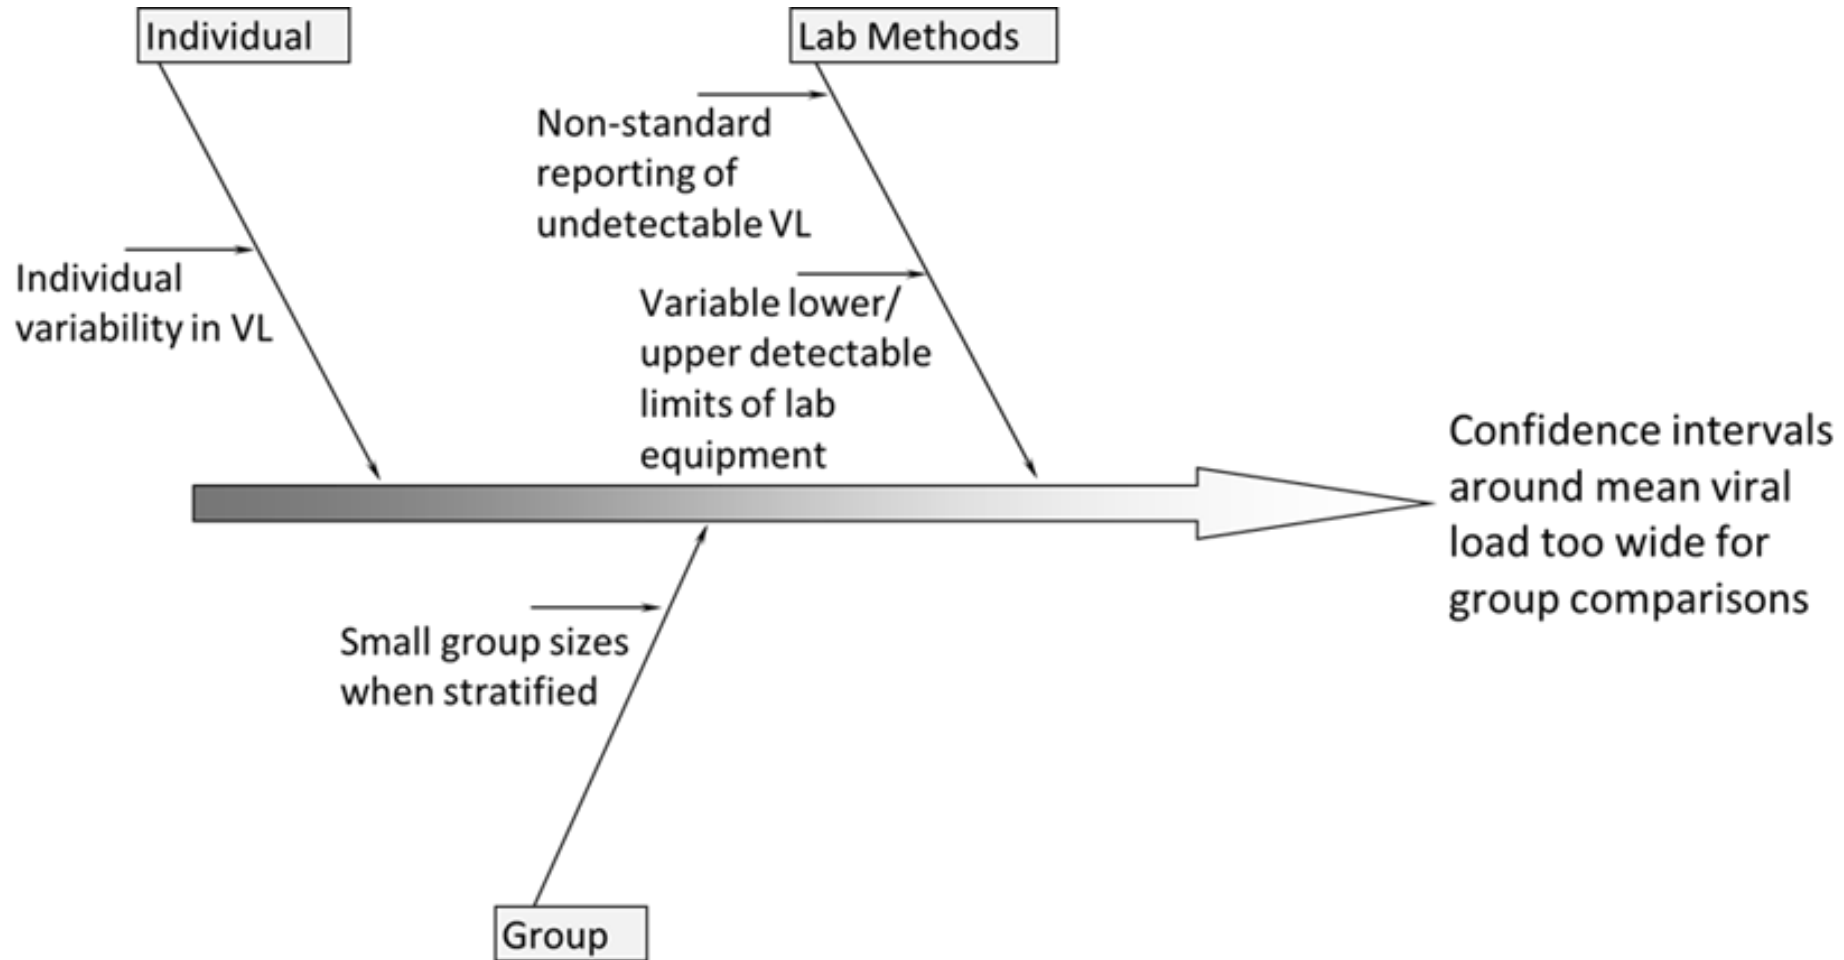

- The Ryan White/HIV Services Program in the Indianapolis transitional grant area (TGA) has historically evaluated viral load among residents, but confidence intervals were too wide for group comparisons

*(A confidence interval is a statistical measure of how sure we are about the results)*

# Root Cause Analysis

- Root cause analysis was conducted during the 2016-2017 Part A grant year in order to identify the root causes of wide confidence intervals

# Root Cause Analysis

# Root Cause Analysis

- Findings:
  - Labs are not consistent in their instrumentation and reporting
  - HIV viral load varies widely from person to person and group to group
- Resolution:
  - Viral load results were standardized and evaluated in a manner that helped ensure that statistically significant comparisons could be made

# New Analysis Procedures

- Standardization (CDC recommended<sup>2</sup>):
  - Lower and upper detectable limits (LDL and UDL) are collected from labs
  - Results lower than the LDL are standardized to a number equal to half the reported LDL
    - Exp. **Report of 0 from a lab with a LDL = 20 would be standardized to 10 c/mL**
  - Results higher than the UDL are standardized to a number of UDL + 1
    - Exp. **Report of >1,000,000 from a lab with a UDL = 750,000 would be standardized to 750,001 c/mL**
  - Where LDL and/or UDL are missing, results are standardized to the most commonly reported LDL and UDL values for the time period examined

# New Analysis Procedures

- Use of Geometric Mean (GM) versus Arithmetic Mean:
  - GM is a logarithmic transformation calculated by averaging the log transformed values of a set of viral load results
  - This calculated average is then transformed back to the original (linear) scale as it is a more intuitive value
    - *The base used for the log transformation has no effect on the final GM estimate; however, using log base 10 has an advantage by its relationship to the value on the original scale.*
    - **Exp. A value of 2 on the log<sub>10</sub> scale = 100 on the original scale; 3 corresponds to 1,000; 4 to 10,000; and so forth.**
  - *It is important to note that GM is not a true viral load result and should not be construed as anything but a way to compare the viral load of different populations. Arithmetic mean should be provided to reduce confusion.*

# Why These New Procedures?

- Normalizes data by reducing the influence of outlying values such as the extremely high viral loads seen in those newly infected
- Enables evaluation of data covering several orders of magnitude
- Tightens confidence intervals allowing statistically significant comparisons to be made

# Our Analysis & Findings

# SAS Program & R Program

- Originally developed using SAS Enterprise Guide 7.1 to compare geometric mean viral loads using Indianapolis TGA viral load data from eHARS
- Replicated in R 3.4.1 to provide open source option for partners to freely conduct their own analysis
- R program will be made available for use upon request

# More Information on SAS and R

- SAS is a commercial software developed by SAS Institute with a strong variety of statistical evaluation methods, but can be cost-prohibitive for many organizations
- R is the open source alternative to SAS and is free for use with over 15,000 packages available for use in the Comprehensive R Archive Network (CRAN) commonly used with the RStudio integrated development environment (IDE)
- R and RStudio are available for download here:  
<https://www.rstudio.com/products/rstudio/download/>
- The list of all available R packages in CRAN is available here: [https://cran.r-project.org/web/packages/available\\_packages\\_by\\_name.html](https://cran.r-project.org/web/packages/available_packages_by_name.html)
- Packages can be easily installed and loaded with two commands via the R shell.  
Example:
  - `> install.packages("ggplot2")`  
`> library(ggplot2)`

# Input

- Standardized HIV data with year, viral load, and additional variables of interest for comparison such as county, retention status, birth sex, and race
  - We have utilized eHARS Person and Labs data for Indy TGA

# Output

- Community arithmetic and geometric mean viral loads with 95% CI for variables known among all PLWH/A in the TGA and by following categories:
  - Race, Age, Gender, County, Risk, Retention in Care status, Ryan White status, and Facility

# Geographic Area Included

**4,513** HIV-positive TGA residents who received HIV-related medical care at least once were included in the analysis

# Arithmetic vs. Geometric Mean Results

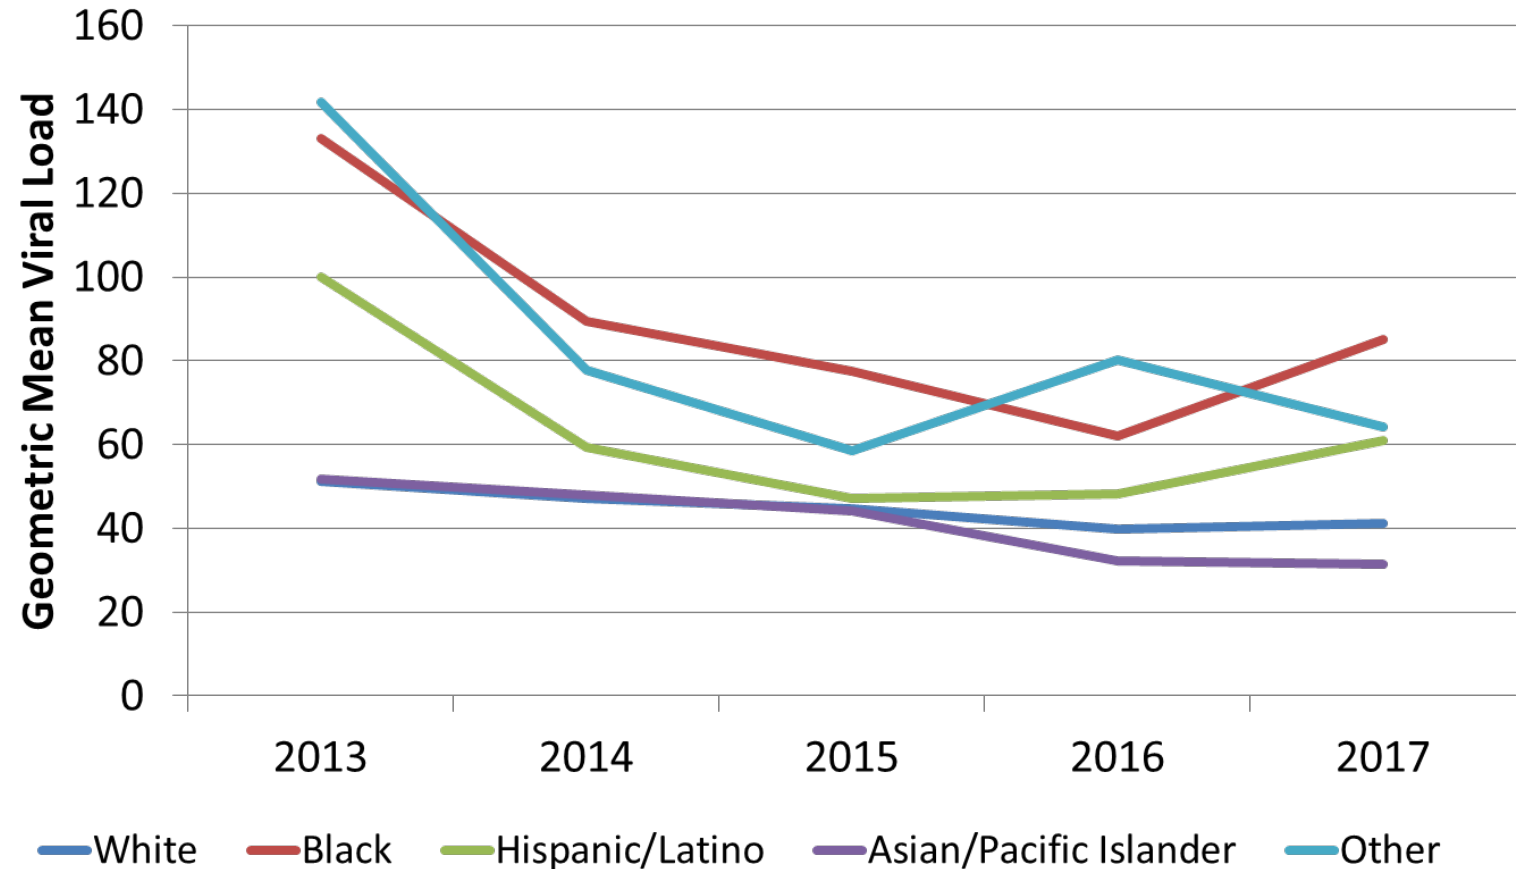

- We can see that viral loads were *statistically* lower in 2017 than in 2013 using geometric mean (right). This difference would not have been identified using only arithmetic mean

# Results

- Geometric mean viral load of African Americans was **twice** that of their white peers
- Hispanic/Latino viral load was about **50% higher** than that of white PLWH

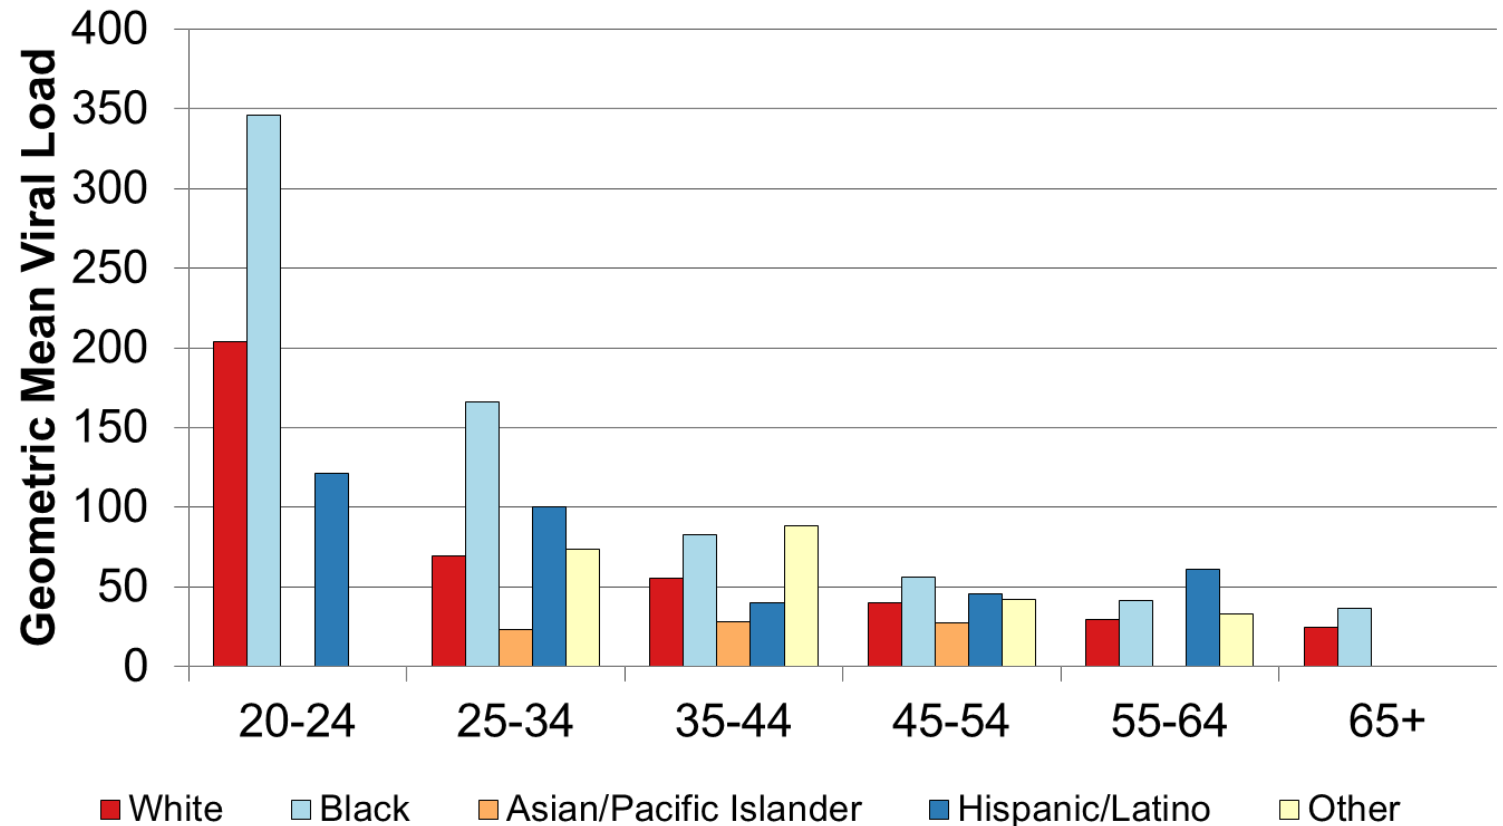

Geometric Mean Viral Load (c/mL) among TGA Residents with at Least One Viral Load Test, by Race/Ethnicity: 2013-2017

# Results

- African Americans do not differ significantly from other racial groups in middle to late adulthood
- 20-34 year old African Americans differs significantly from that of their peers

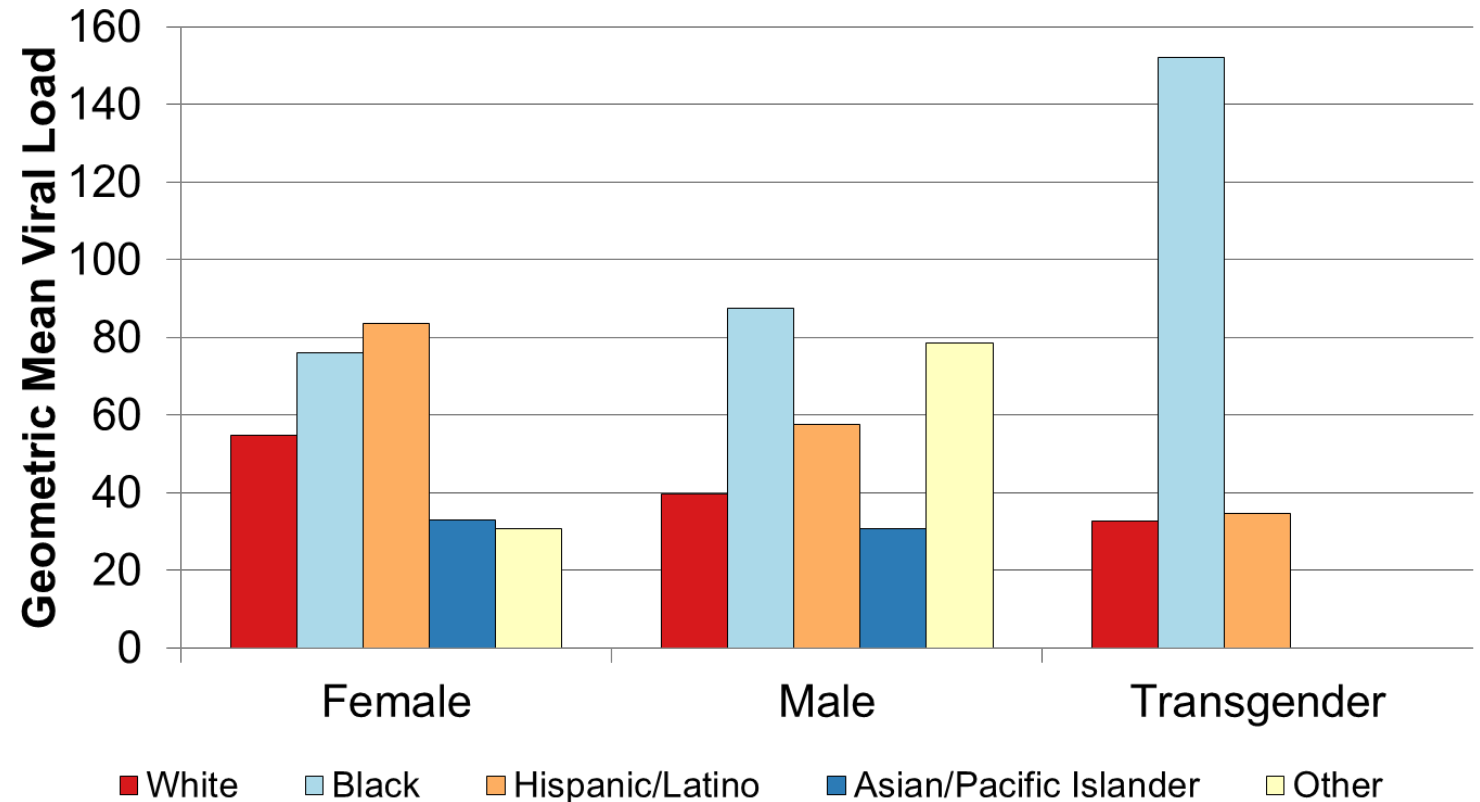

Geometric Mean Viral Load (c/mL) among TGA Residents with at Least One Viral Load Test, by Race/Ethnicity and Age: 2017

# Results

- Geometric mean viral load of African American men was more than **twice** that of white men during 2017
- Viral load among females was not significantly different from males

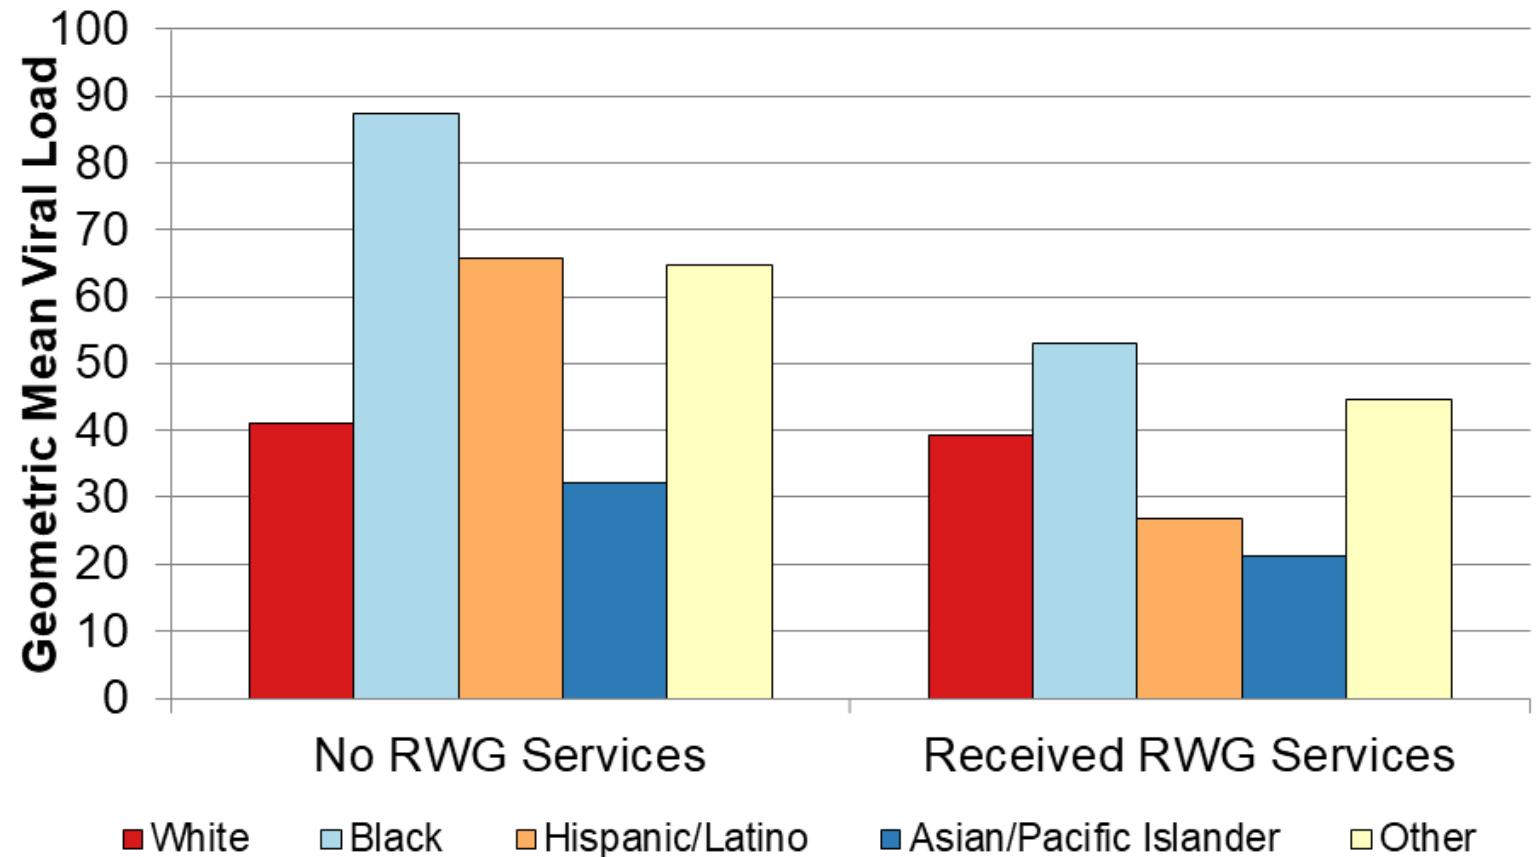

Geometric Mean Viral Load (c/mL) among TGA Residents with at Least One Viral Load Test, by Race/Ethnicity and Gender: 2017

# Results

- Geometric mean viral load among all racial/ethnic minorities not utilizing Ryan White services in the Indy TGA was higher than among Ryan White clients
- This difference was not found among white PLWH in the TGA

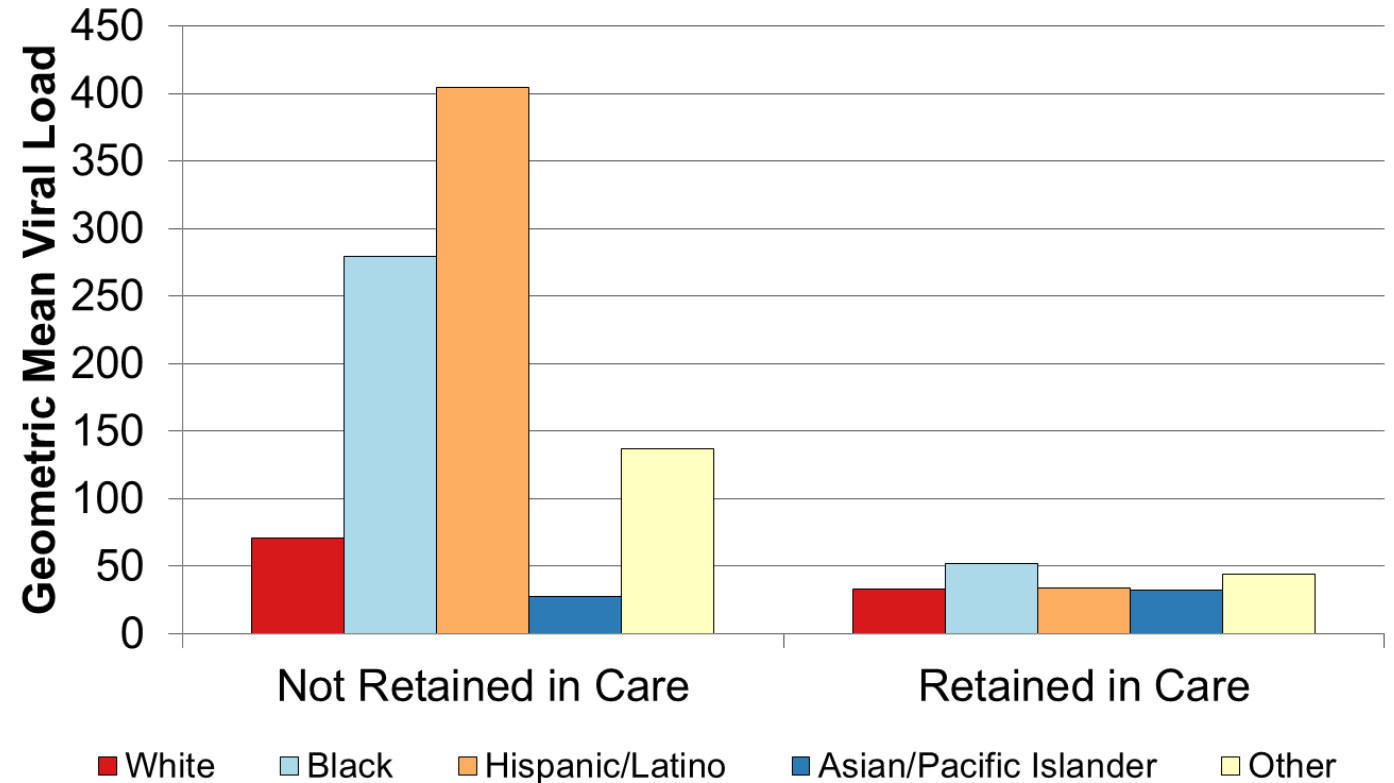

Geometric Mean Viral Load (c/mL) among TGA Residents with at Least One Viral Load Test, by Race/Ethnicity and Ryan White Part A/MAI Client Status: 2017

# Results

- Among individuals not retained in care, Hispanic/Latinos and African Americans experienced the highest viral loads
- ***Even when retained in care,*** African Americans experienced poorer outcomes, with viral loads **50% higher** than their white peers

Geometric Mean Viral Load (c/mL) among TGA Residents with at Least One Viral Load Test, by Race/Ethnicity and Retention in Care Status: 2017

# Conclusions

- Using data standardization and geometric mean analysis has allowed us to **make better comparisons between groups**
- Allows for **better allocation of resources to target interventions** to those most likely to have increased viral loads
